

Isometry of LET Grafts Across Tibial Insertion Sites with Cadaveric and Intraoperative Analysis of Femoral Landmark Using Fluoroscopic Guidance

Zachary R Oppenheim, Edouard J Augustin, Divesh Sachdev, Matthew Henriques, Adam Blair Yanke

INTRODUCTION: Lateral extraarticular tenodesis (LET) enhances rotational stability and reduces graft failure when added to ACL reconstruction. While optimal femoral placement has been studied, the effect of varying tibial insertion sites on graft length change across flexion angles remains unclear. This study characterizes graft isometry relative to tibial attachment positions using a reproducible femoral landmark identified via intraoperative fluoroscopy.

METHODS: Patients who underwent lateral extra-articular tenodesis from a single surgeon were retrospectively reviewed. Intraoperative, true-lateral, x-ray images with the femoral shaft visible and identifiable femoral LET insertion points were analyzed. The LET placement was described relative to the posterior femur and intersection of the posterior femoral condyles. Subsequently, 10 fresh-frozen cadaveric specimens were dissected. The femoral LET insertion points on all specimens were identified by the same surgeon. Three points were then identified on the anterior border, center, and posterior border of the IT Band at Gerdy's Tubercle. Three-dimensional measurements were then collected using a micro scribe (MicroScribe MX Series Digitizer). The LET placement was described relative to the lateral epicondyle, posterior femur, and posterior condyle. The total distance from each tibial insertion to the identified LET point on the femur was calculated at 0, 15, 30, 45, 60, and 90 degrees of flexion.

RESULTS: A total of 7 intraoperative and 10 cadaveric images were assessed, with LET insertion points identified by a single surgeon shown in Figure 1. On cadaveric specimens, the LET insertion was located on average 7.40 ± 1.56 mm proximal and 3.89 ± 2.11 mm posterior to the lateral epicondyle (Table 1). LET graft length changes significantly varied by tibial insertion location at lower knee flexion angles. One-way ANOVA revealed significant differences between anterior, central, and posterior regions at 0° ($p = 0.0004$), 15° ($p = 0.0008$), 30° ($p = 0.0018$), and 45° ($p = 0.0051$), but not at 60° ($p = 0.053$) or 90° ($p = 0.288$). Post-hoc Tukey tests showed anterior insertions had significantly greater length changes than posterior insertions at 0° , 15° , and 30° ($p \leq 0.003$), with similar differences observed between anterior and central regions, while central versus posterior comparisons were not significant (Table 2). The average insertion point distances at 0° and 90° differed significantly for the anterior (10.3 ± 5.09 mm, $p < 0.001$) and central (4.13 ± 5.76 mm, $p = 0.049$) regions, but not posterior (0.94 ± 0.15 mm, $p = 0.152$) (Table 3). Post-hoc analysis indicated significant length change from 0° to 90° between anterior and posterior points ($p = 0.001$), with anterior versus central differences approaching significance ($p = 0.051$).

DISCUSSION AND CONCLUSION:

This study identifies a reproducible femoral LET insertion (~7.4 mm proximal and 3.9 mm posterior to the lateral epicondyle) using fluoroscopy and demonstrates that tibial position significantly affects graft isometry in early flexion. Posterior tibial placement maintains near-isometry, minimizing length variation through 0° – 90° flexion. These findings complement prior work showing posterior femoral placement reduces overconstraint, offering a comprehensive approach to graft positioning. Use of posterior tibial fixation may reduce graft tension variability and overconstraint risk, potentially improving clinical outcomes—particularly in high-risk or revision ACL reconstruction. Further clinical correlation is warranted to assess improvements in graft failure rates and patient-reported outcomes.

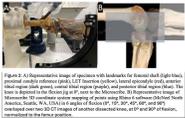

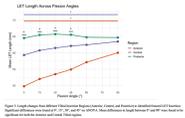

Figure 2. Intraoperative image of a knee joint showing the femoral shaft and the lateral epicondyle. A yellow line indicates the femoral LET insertion point, which is approximately 7.4 mm proximal and 3.9 mm posterior to the lateral epicondyle.

Landmark	Mean (SD)	Minimum	Maximum
Lateral Epicondyle	7.40 (1.56)	5.06	9.52
Posterior Condyle	3.89 (2.11)	1.78	6.02
Gerdy's Tubercle	6.94 (1.15)	6.00	7.88
Intersection of IT Band	6.94 (1.15)	6.00	7.88
Posterior Femoral Condyle	3.89 (2.11)	1.78	6.02

Flexion Angle	Anterior	Central	Posterior
0°	10.3 (5.09)	4.13 (5.76)	0.94 (0.15)
15°	11.5 (5.5)	4.5 (5.8)	1.0 (0.15)
30°	12.7 (6.0)	5.0 (6.0)	1.0 (0.15)
45°	14.0 (6.5)	5.5 (6.5)	1.0 (0.15)
60°	15.0 (7.0)	6.0 (7.0)	1.0 (0.15)
90°	15.4 (7.5)	9.9 (7.5)	1.0 (0.15)

Comparison	Mean Change (mm)	p-value
Anterior vs Posterior	14.5	0.001
Anterior vs Central	11.3	0.051
Central vs Posterior	8.9	0.152
